

The coalescent

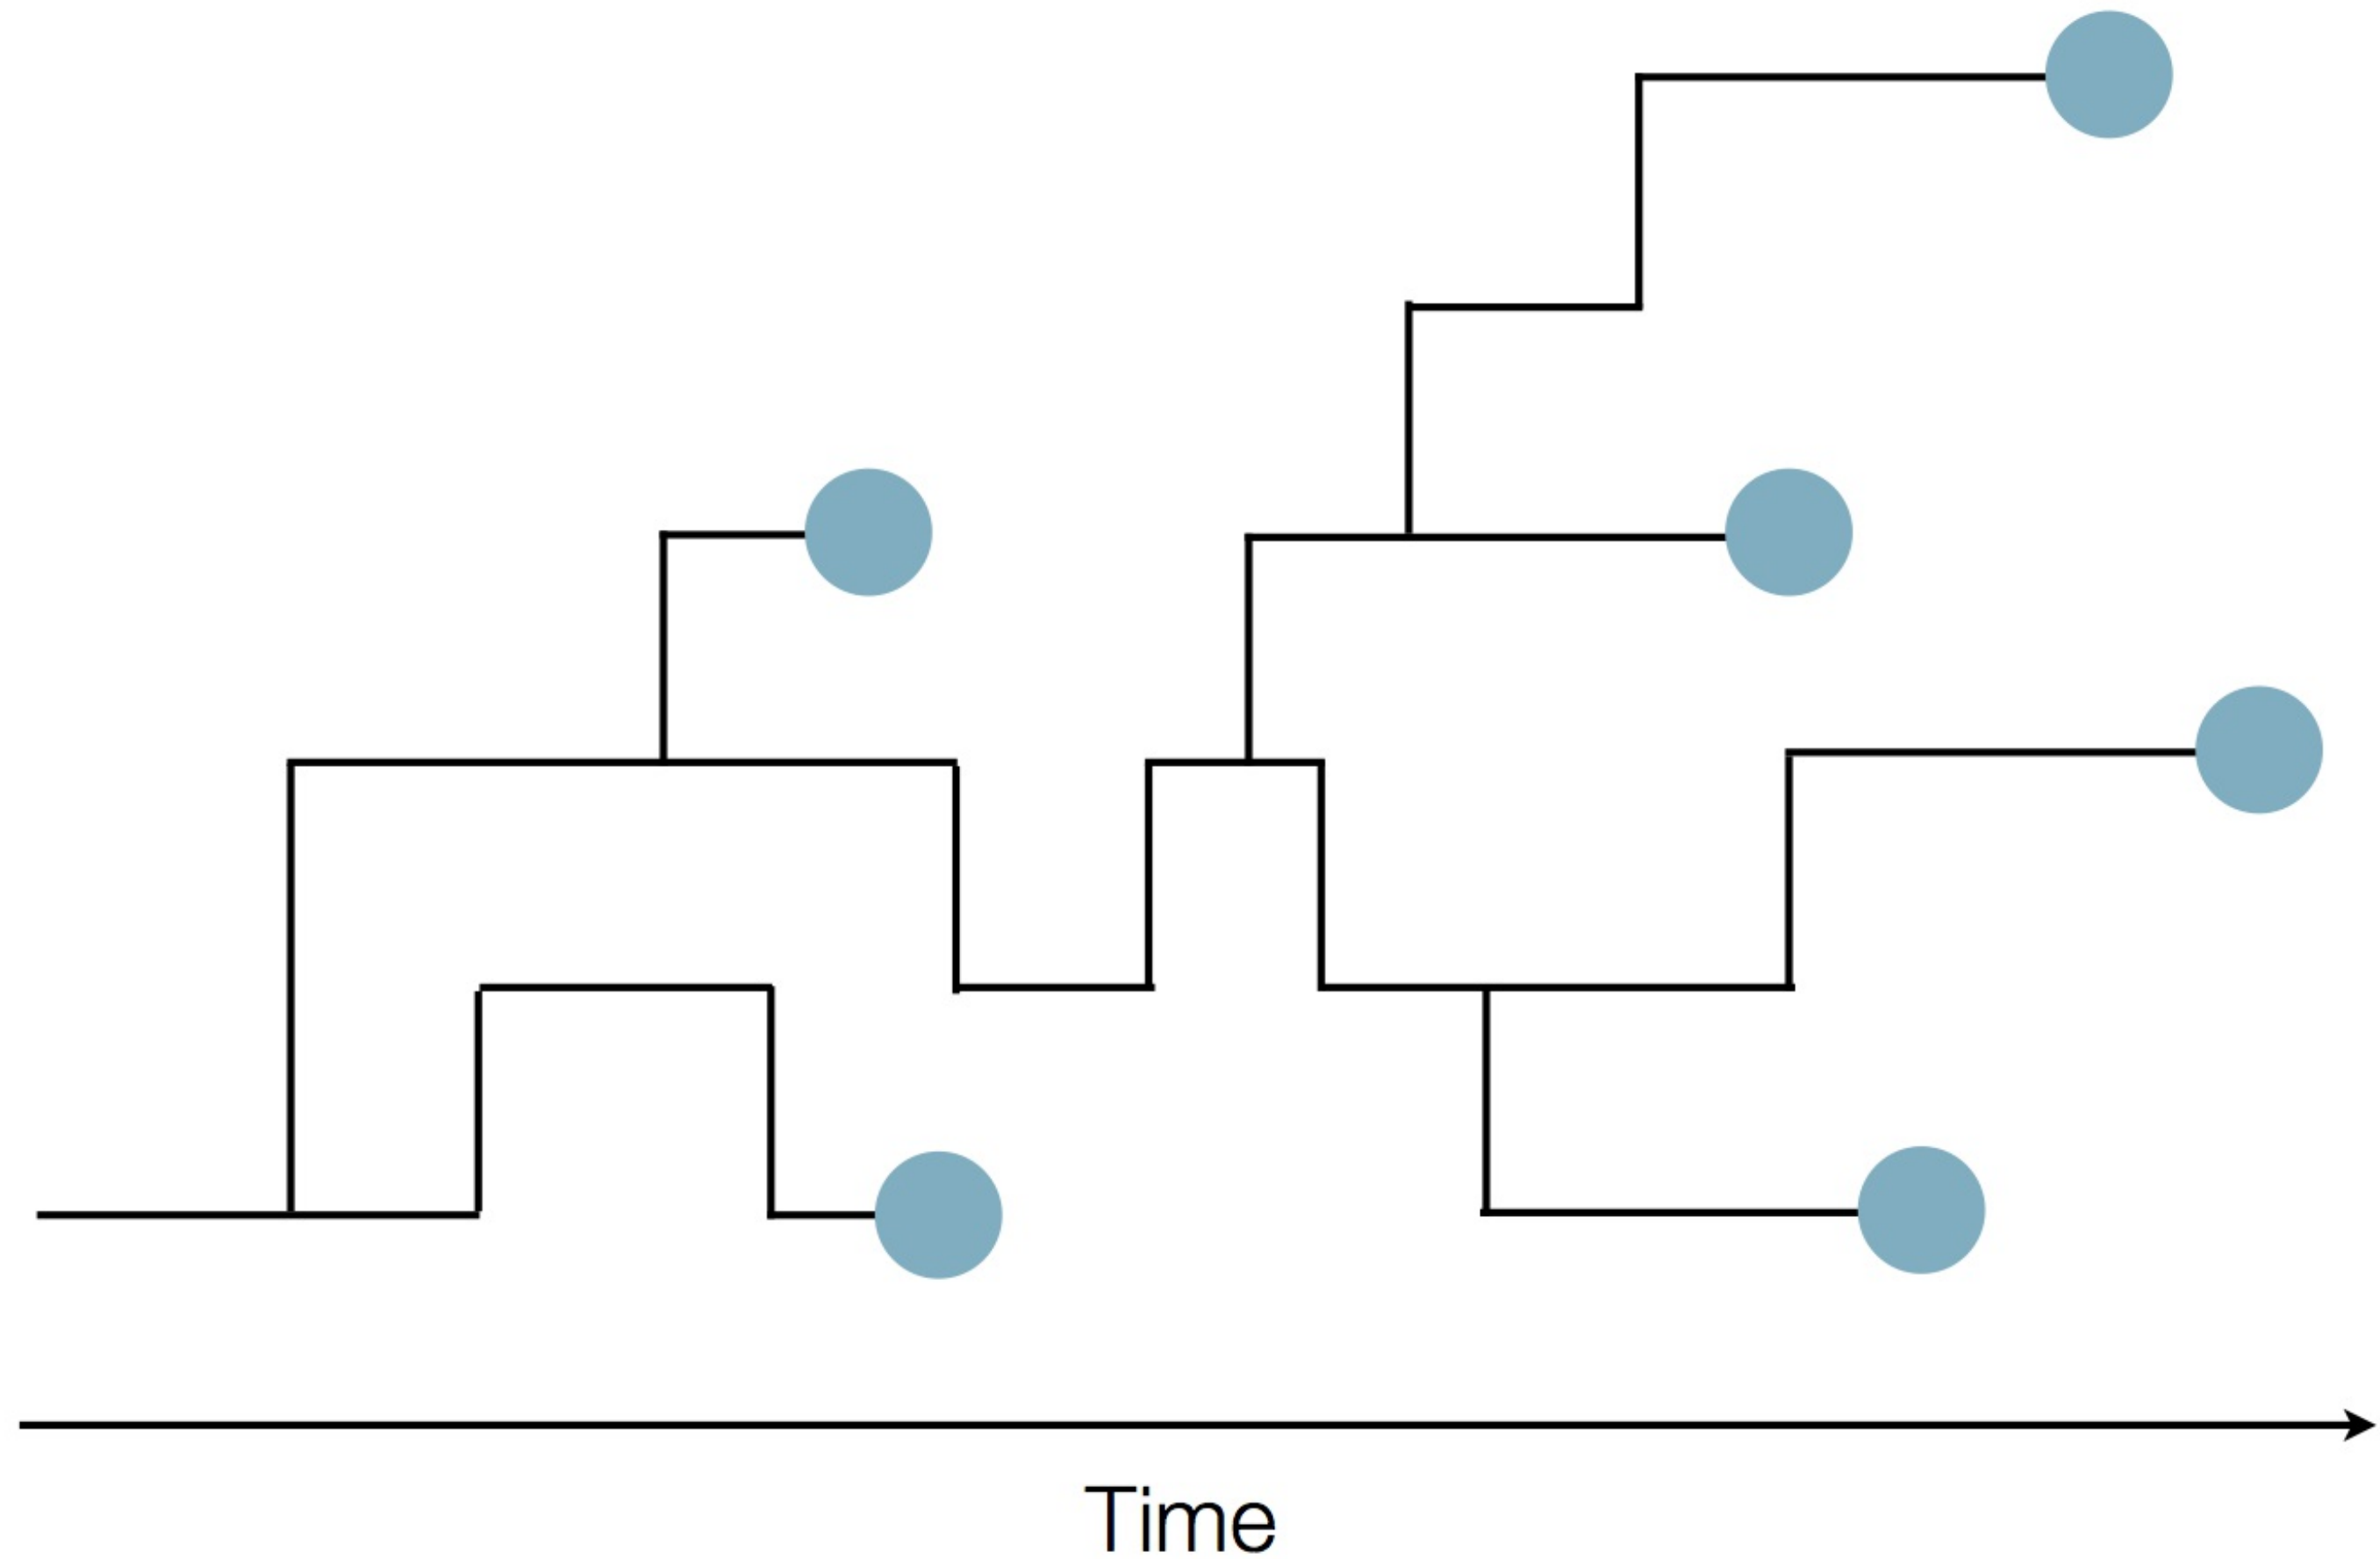

Epidemic process

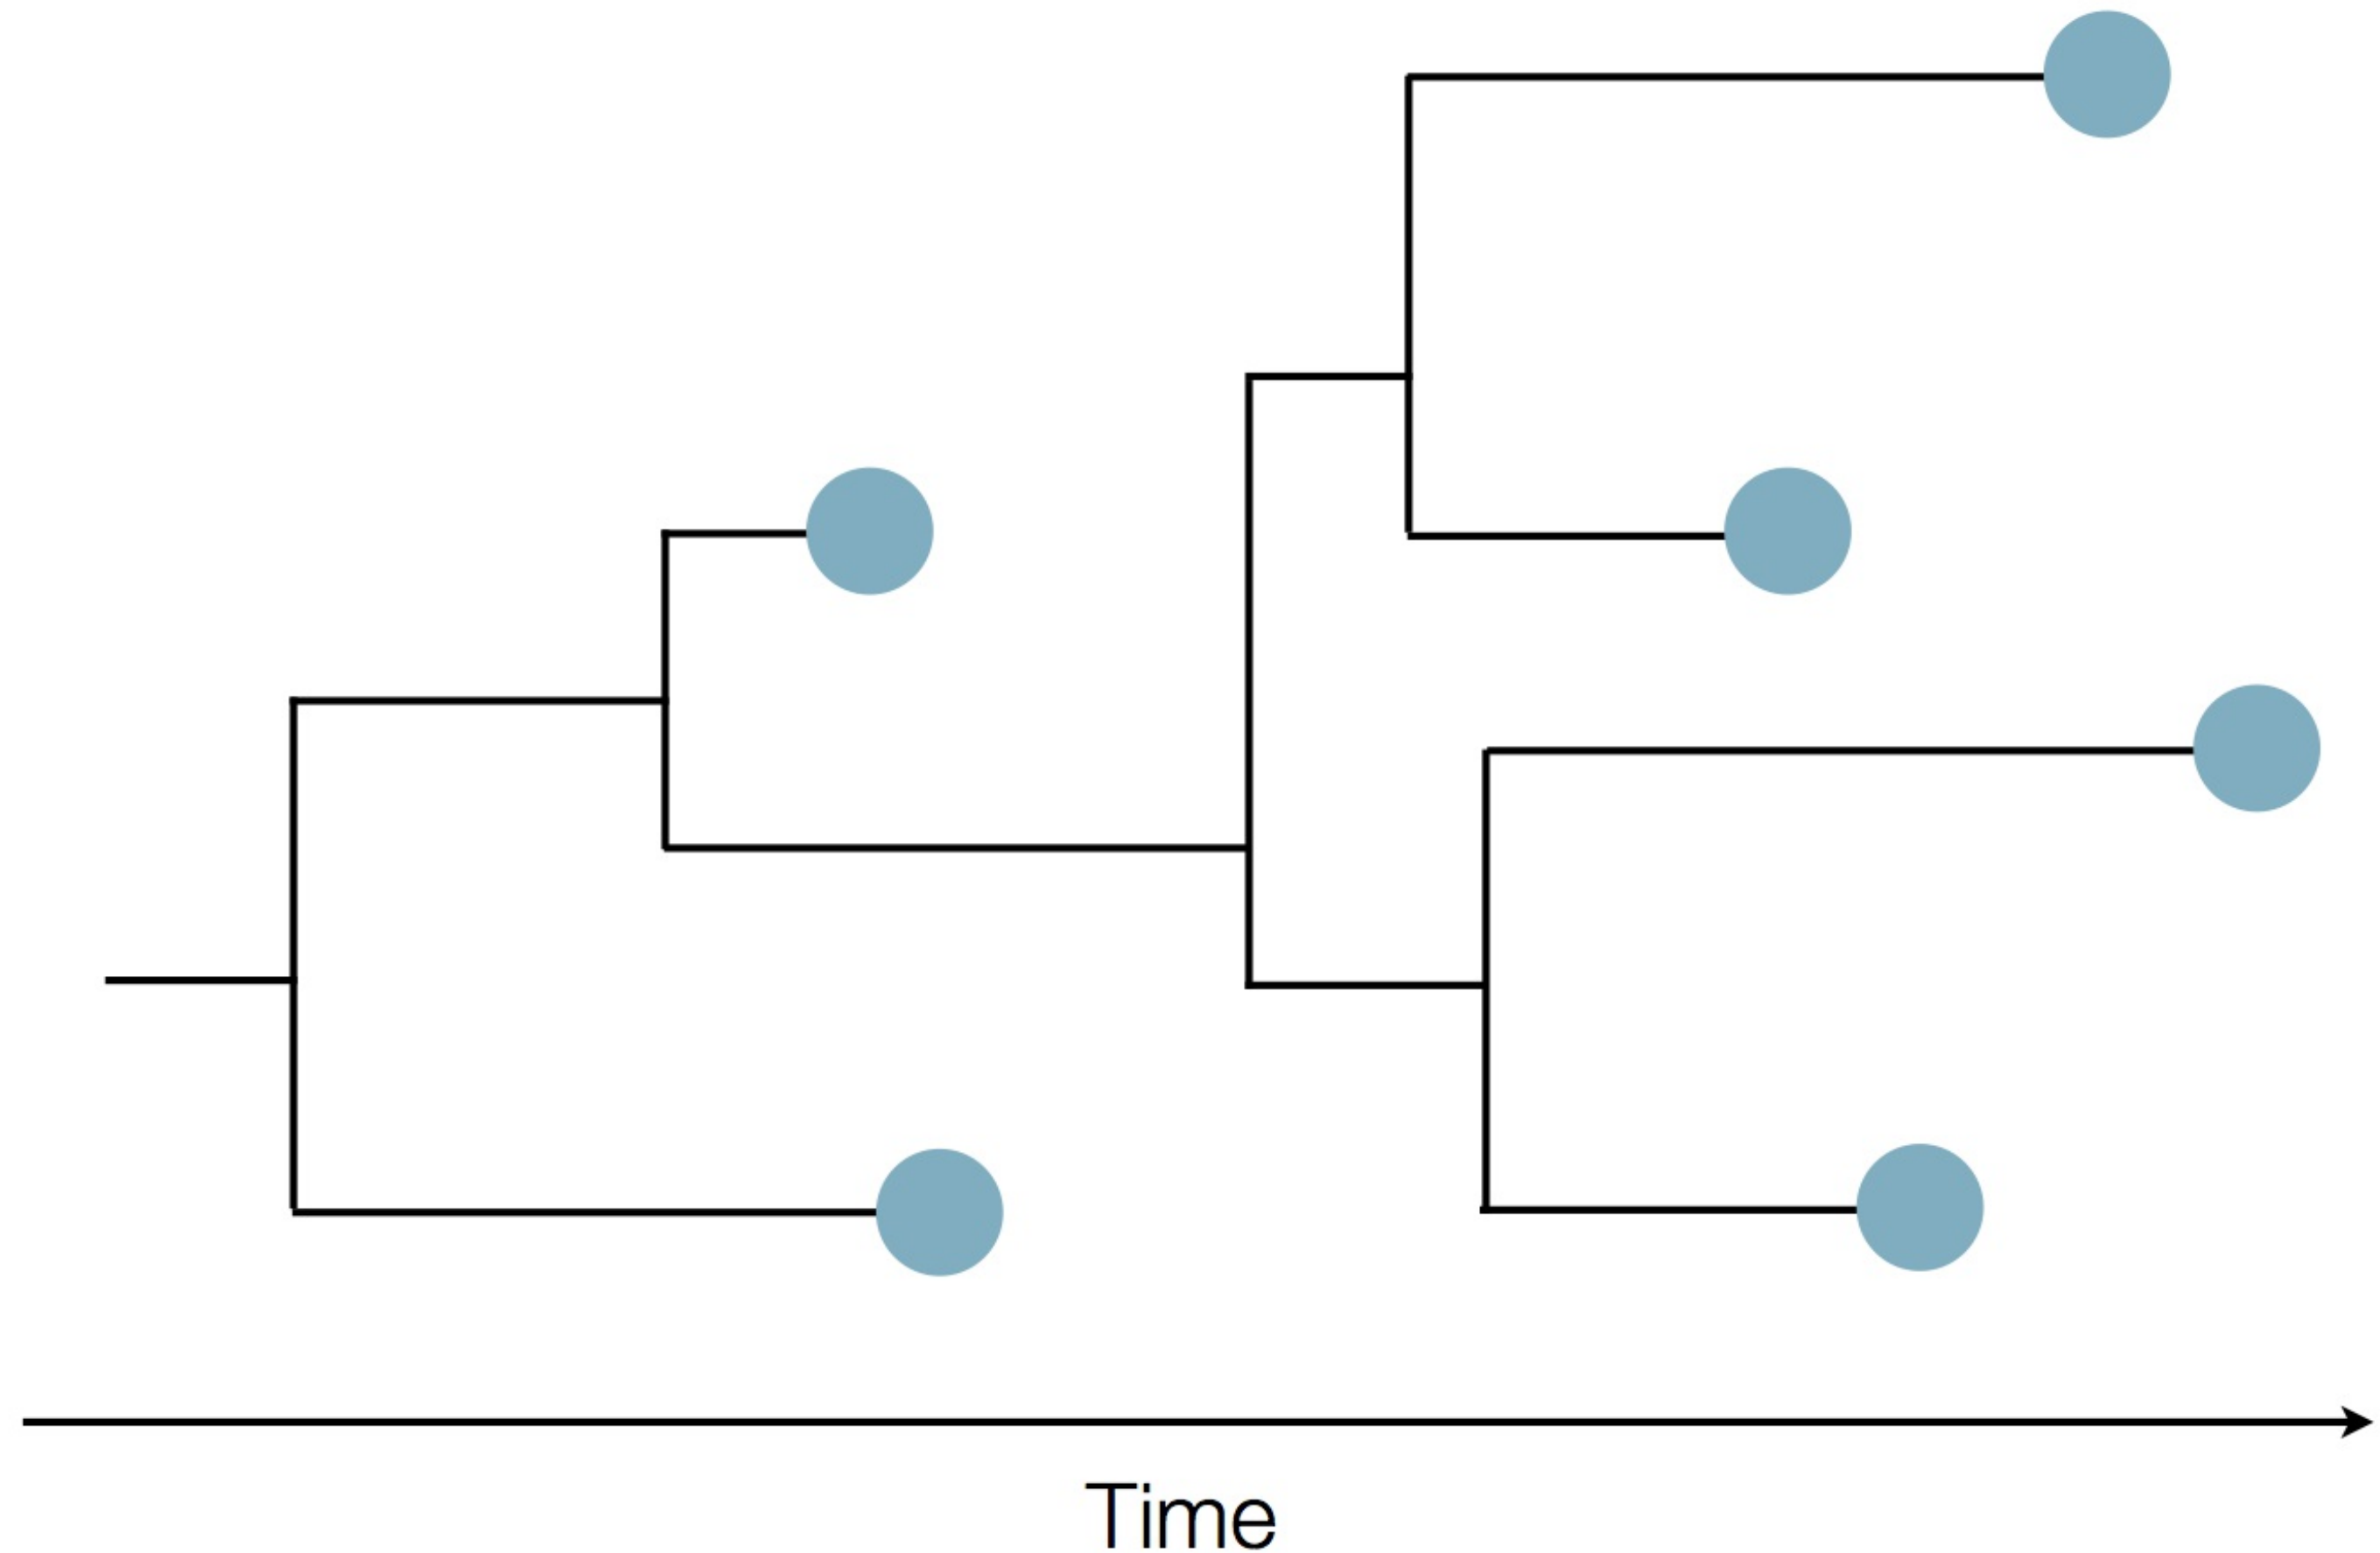

Sample some individuals

Sequence and determine phylogeny

Sequence and determine phylogeny

Wright-Fisher process

Sample some individuals

Each generation coalescence may occur

Each generation coalescence may occur

Each generation coalescence may occur

Each generation coalescence may occur

WHAT WOULD
YOU SAY IS
YOUR BIGGEST
WEAKNESS?

PROBABLY THAT I'M
A GIANT TANGLE OF
PARTS THAT DON'T
ALWAYS WORK RIGHT,
SO I CAN DIE EASILY.

BIGGEST STRENGTH?

THERE WILL COME A
DAY WHEN I'M EITHER
AN ANCESTOR TO ALL
LIVING HUMANS, OR
TO *NONE* OF THEM.

WHERE DO YOU SEE
YOURSELF IN FIVE YEARS?

PROBABLY NOT THE
ANCESTOR OF ALL
LIVING HUMANS YET.
BUT YOU NEVER KNOW!

Set of coalescent intervals

Per-generation probability of coalescence

$$\Pr(\text{coal} \mid i = 2) = \frac{1}{N}$$

Probability of first lineage picking an arbitrary parent is 1, while the probability of the 2nd lineage picking the same parent is $\frac{1}{N}$.

Probability of coalescence scales inversely with population size.

Per-generation probability of coalescence

$$\Pr(\text{coal}) = \binom{i}{2} \frac{1}{N} = \frac{i(i-1)}{2N}$$

There are $\binom{i}{2}$ ways pairs of lineages can pick the same parent.

Probability of coalescence scales quadratically with lineage count.

Expected waiting time to coalescence

$$\mathbf{E}[T_i] = \frac{2N}{i(i-1)}$$

This is a **geometric distribution**. If each generation there is a $\frac{1}{x}$ probability of an event occurring, we expect to wait \mathbf{x} generations for the event to occur.

Continuous time limit

With per-generation probability of an event $\frac{1}{x}$ small, but many generations, then the discrete time geometric distribution approximates to a continuous time **exponential distribution**. Thus, we assume T_i to be exponentially distributed with mean

$$\mathbf{E}[T_i] = \frac{2N}{i(i-1)}.$$

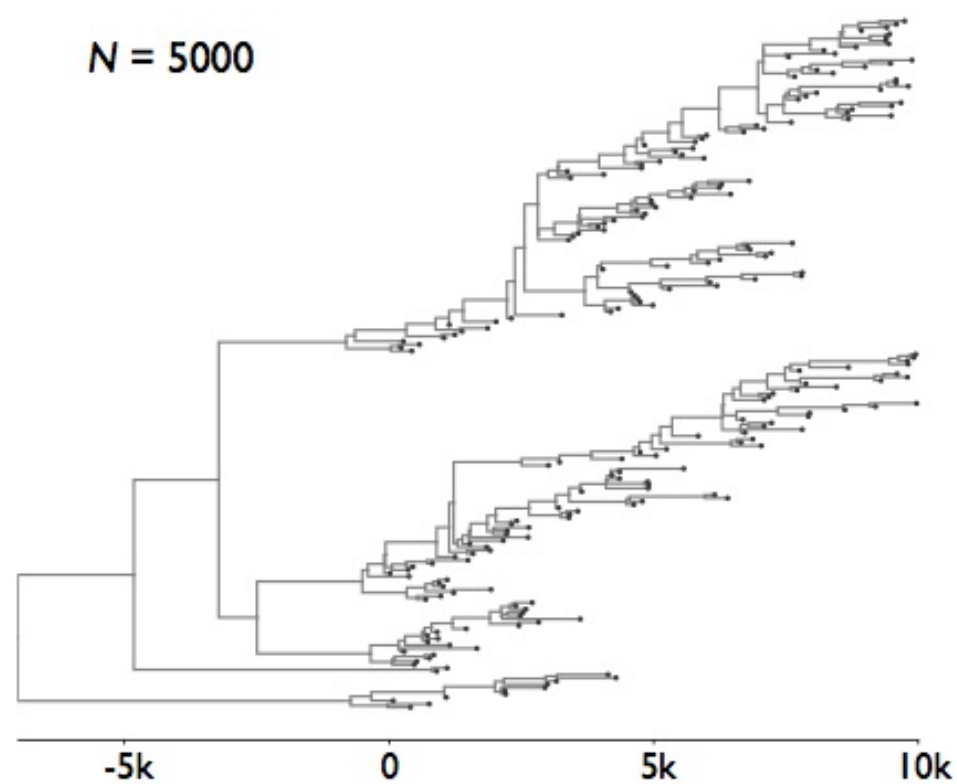

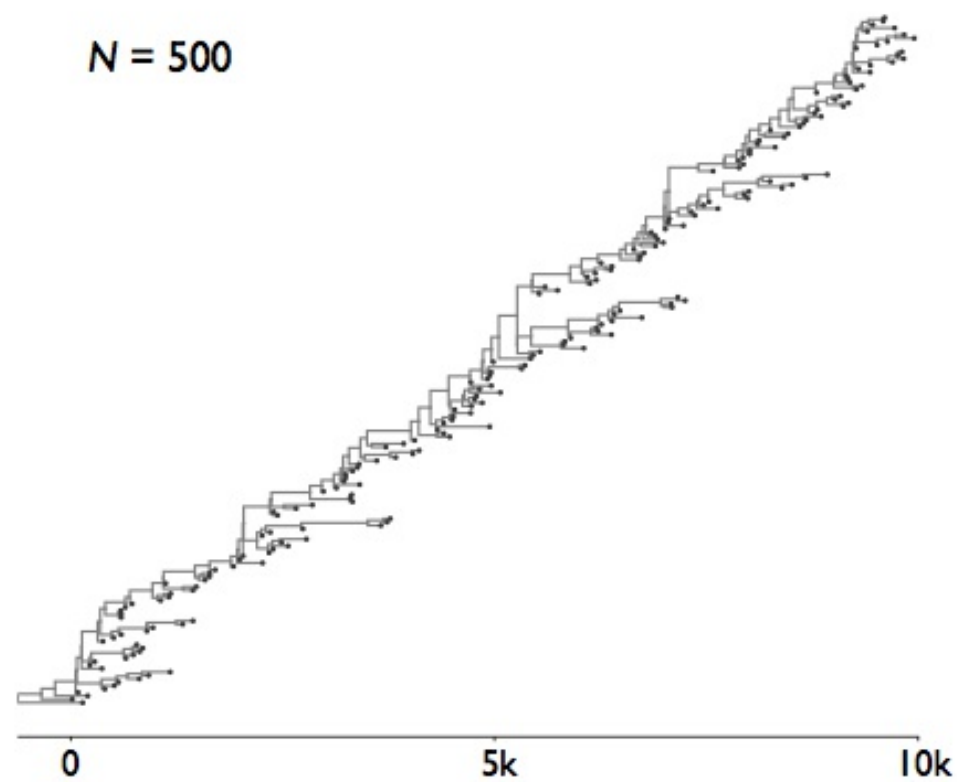

Set of coalescent intervals with waiting times

Gives coalescent trees their distinctive shape

Rate of coalescence scales with population size N

Visualization of the coalescent process

Pairwise genetic diversity

$$E[T_2] = N$$

Gives $2N$ generations for mutations to occur

π is number of substitutions per site between two random individuals

$$E[\pi] = 2N\mu \quad \text{where } \mu \text{ is mutations per site per generation}$$

$$E[\pi] = 2N\tau\mu \quad \text{where } \mu \text{ is mutations per site per year and} \\ \tau \text{ is years per generation}$$

Time to the most recent common ancestor (TMRCA)

$$T_{\text{MRCA}} = \sum_{i=2}^n T_i \quad \mathbb{E}[T_i] = \frac{2N}{i(i-1)}$$

$$\mathbb{E}[T_{\text{MRCA}}] = \sum_{i=2}^n \frac{2N}{i(i-1)}$$

$$= 2N \sum_{i=2}^n \left(\frac{1}{i-1} - \frac{1}{i} \right)$$

$$= 2N \left(1 - \frac{1}{2} + \frac{1}{2} - \dots - \frac{1}{n-1} + \frac{1}{n-1} - \frac{1}{n} \right)$$

$$= 2N \left(1 - \frac{1}{n} \right)$$

$$\mathbb{E}[T_{\text{MRCA}}] = \lim_{n \rightarrow \infty} 2N$$

Coalescence patterns can
estimate population
growth/decline

Changing population size alters coalescent rate

Constant size

Growing population

Constant size

Growing population

'Skyline' is flexible demographic model that estimates windows of coalescent rate

Skyline model shows population growth in HCV

Skyline model shows seasonality in flu

Influenza H3N2 from New York state

Interpreting rate of coalescence

These approaches directly estimate the pairwise rate of coalescence λ , which is measured in terms of events per year. Thus, the timescale of coalescence $\frac{1}{\lambda}$ is measured as the expected waiting time in years for two lineages to find a common ancestor.

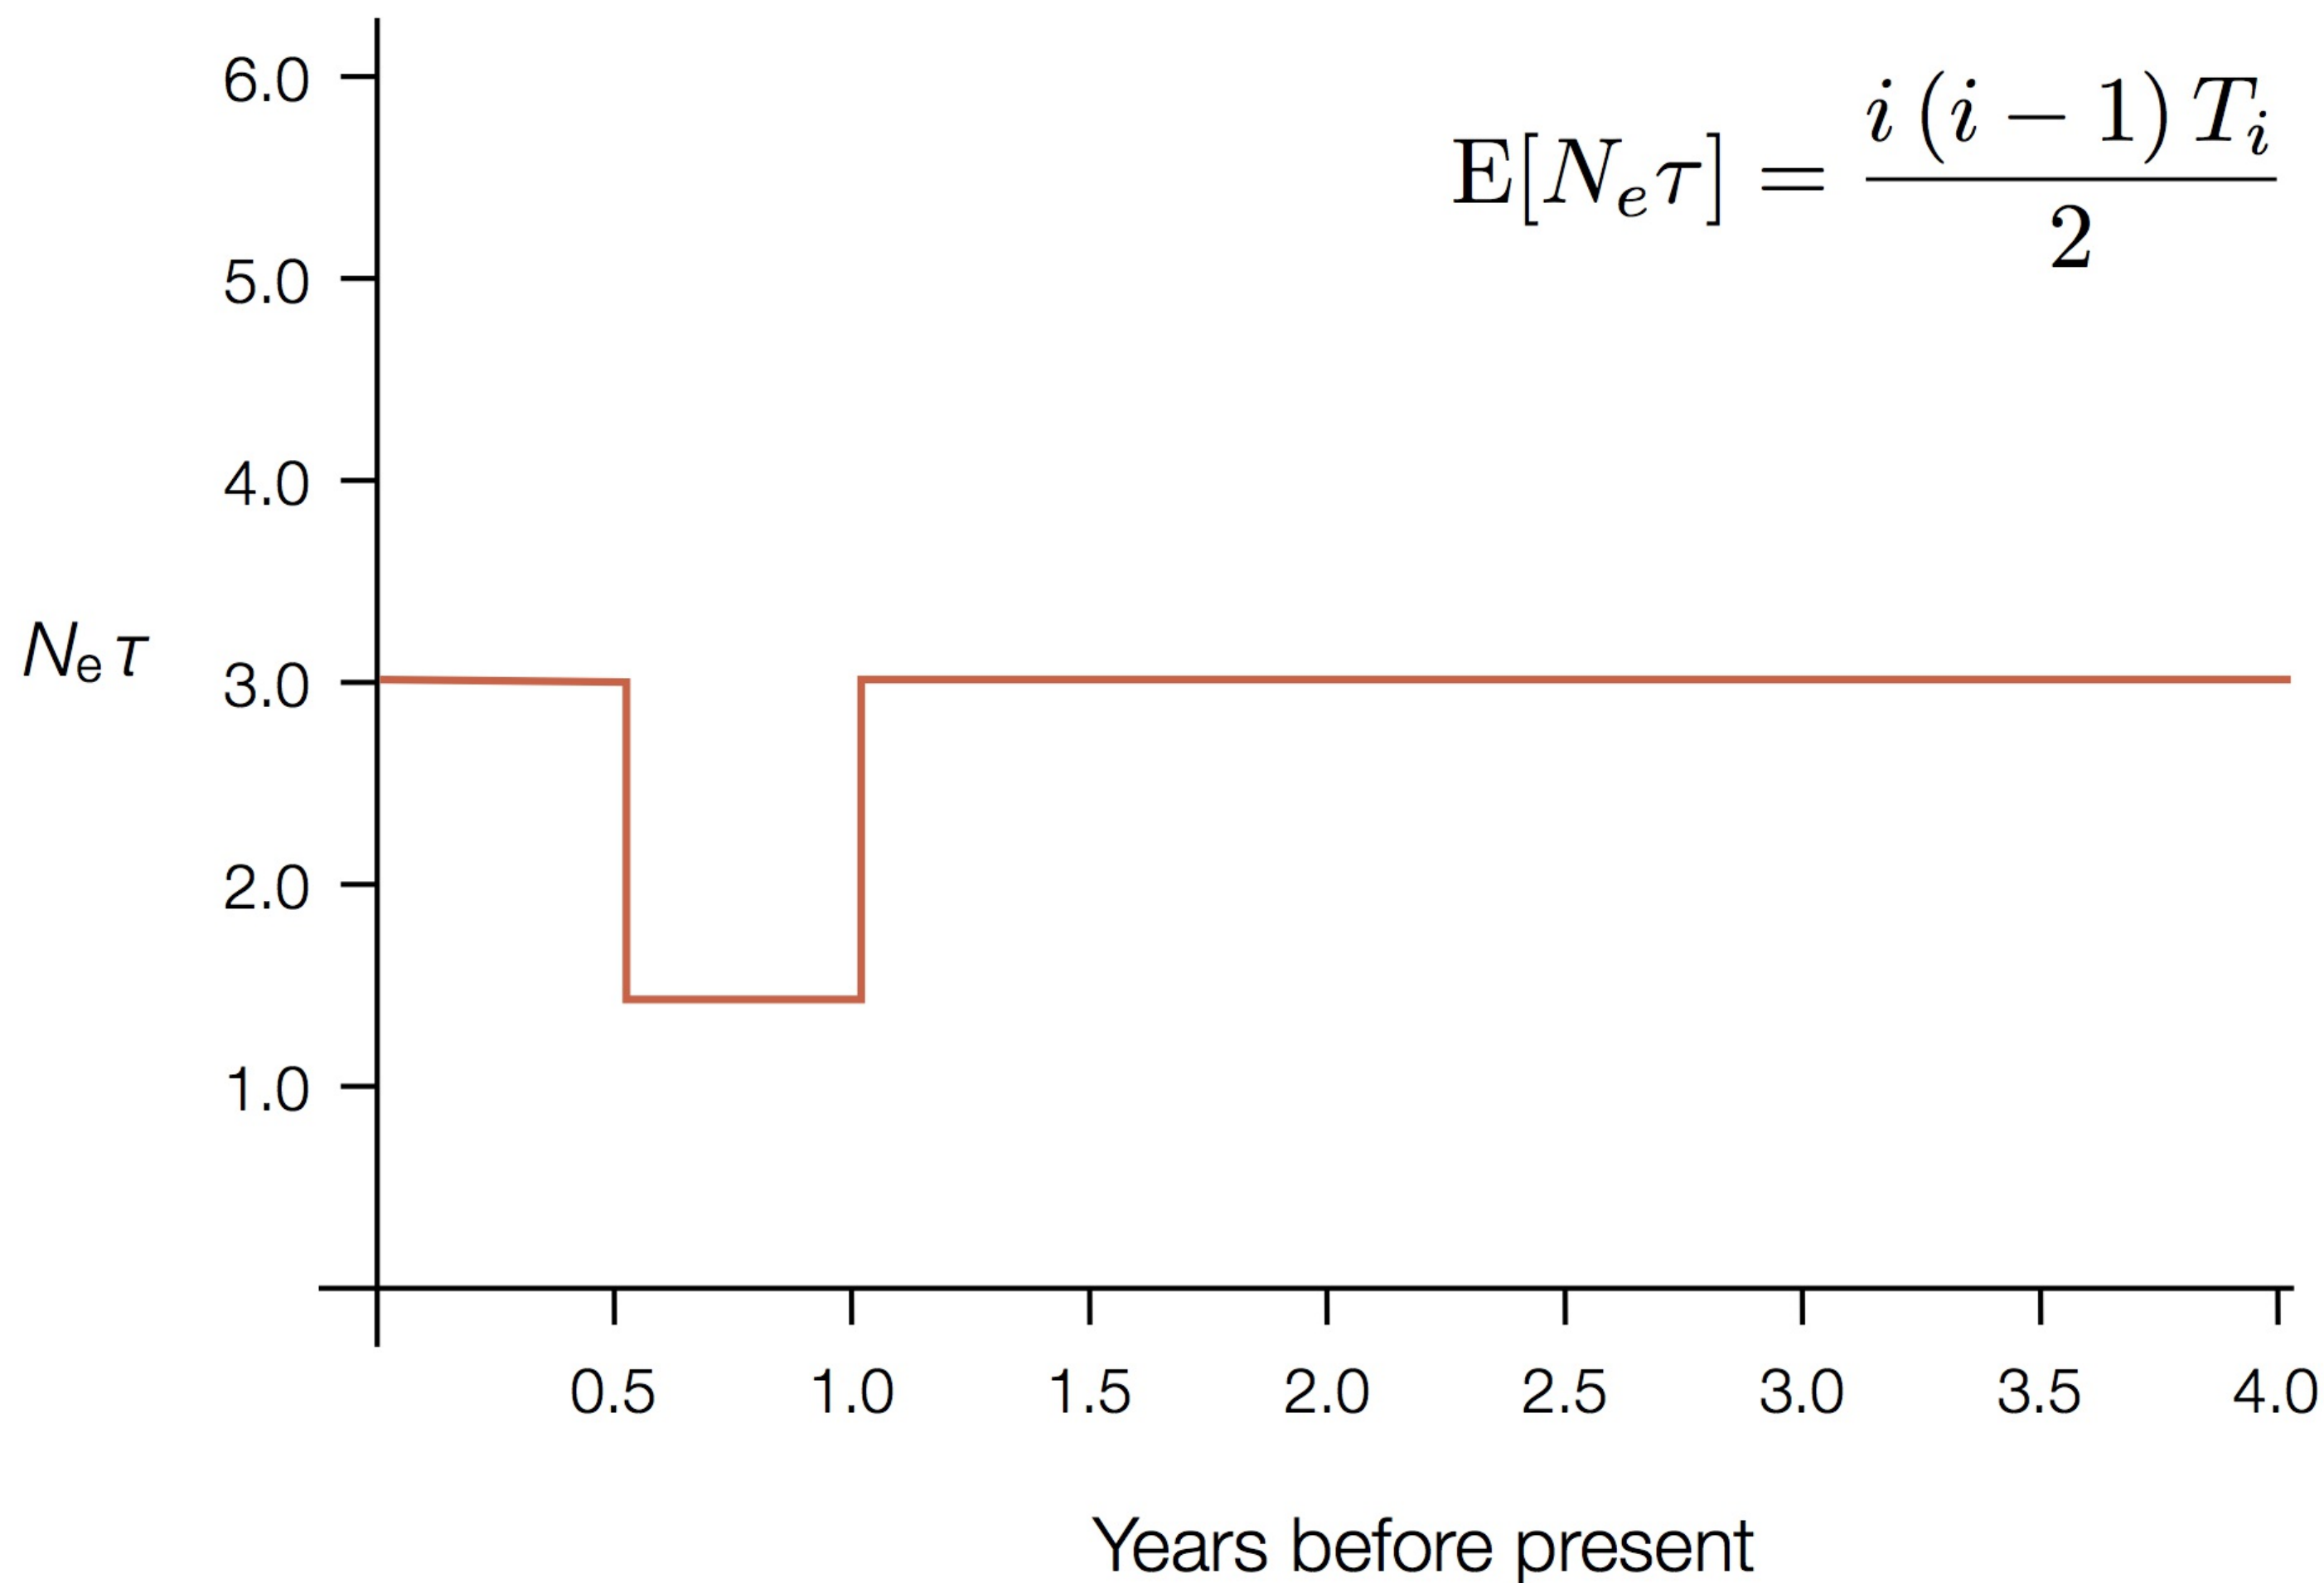

Interpreting rate of coalescence

The timescale of coalescence $\frac{1}{\lambda}$ is equal to $N_e\tau$, where N_e is measured in generations and τ is measured in years per generation. τ acts to rescale time from generations to years.

Example tree

Example skyline plot

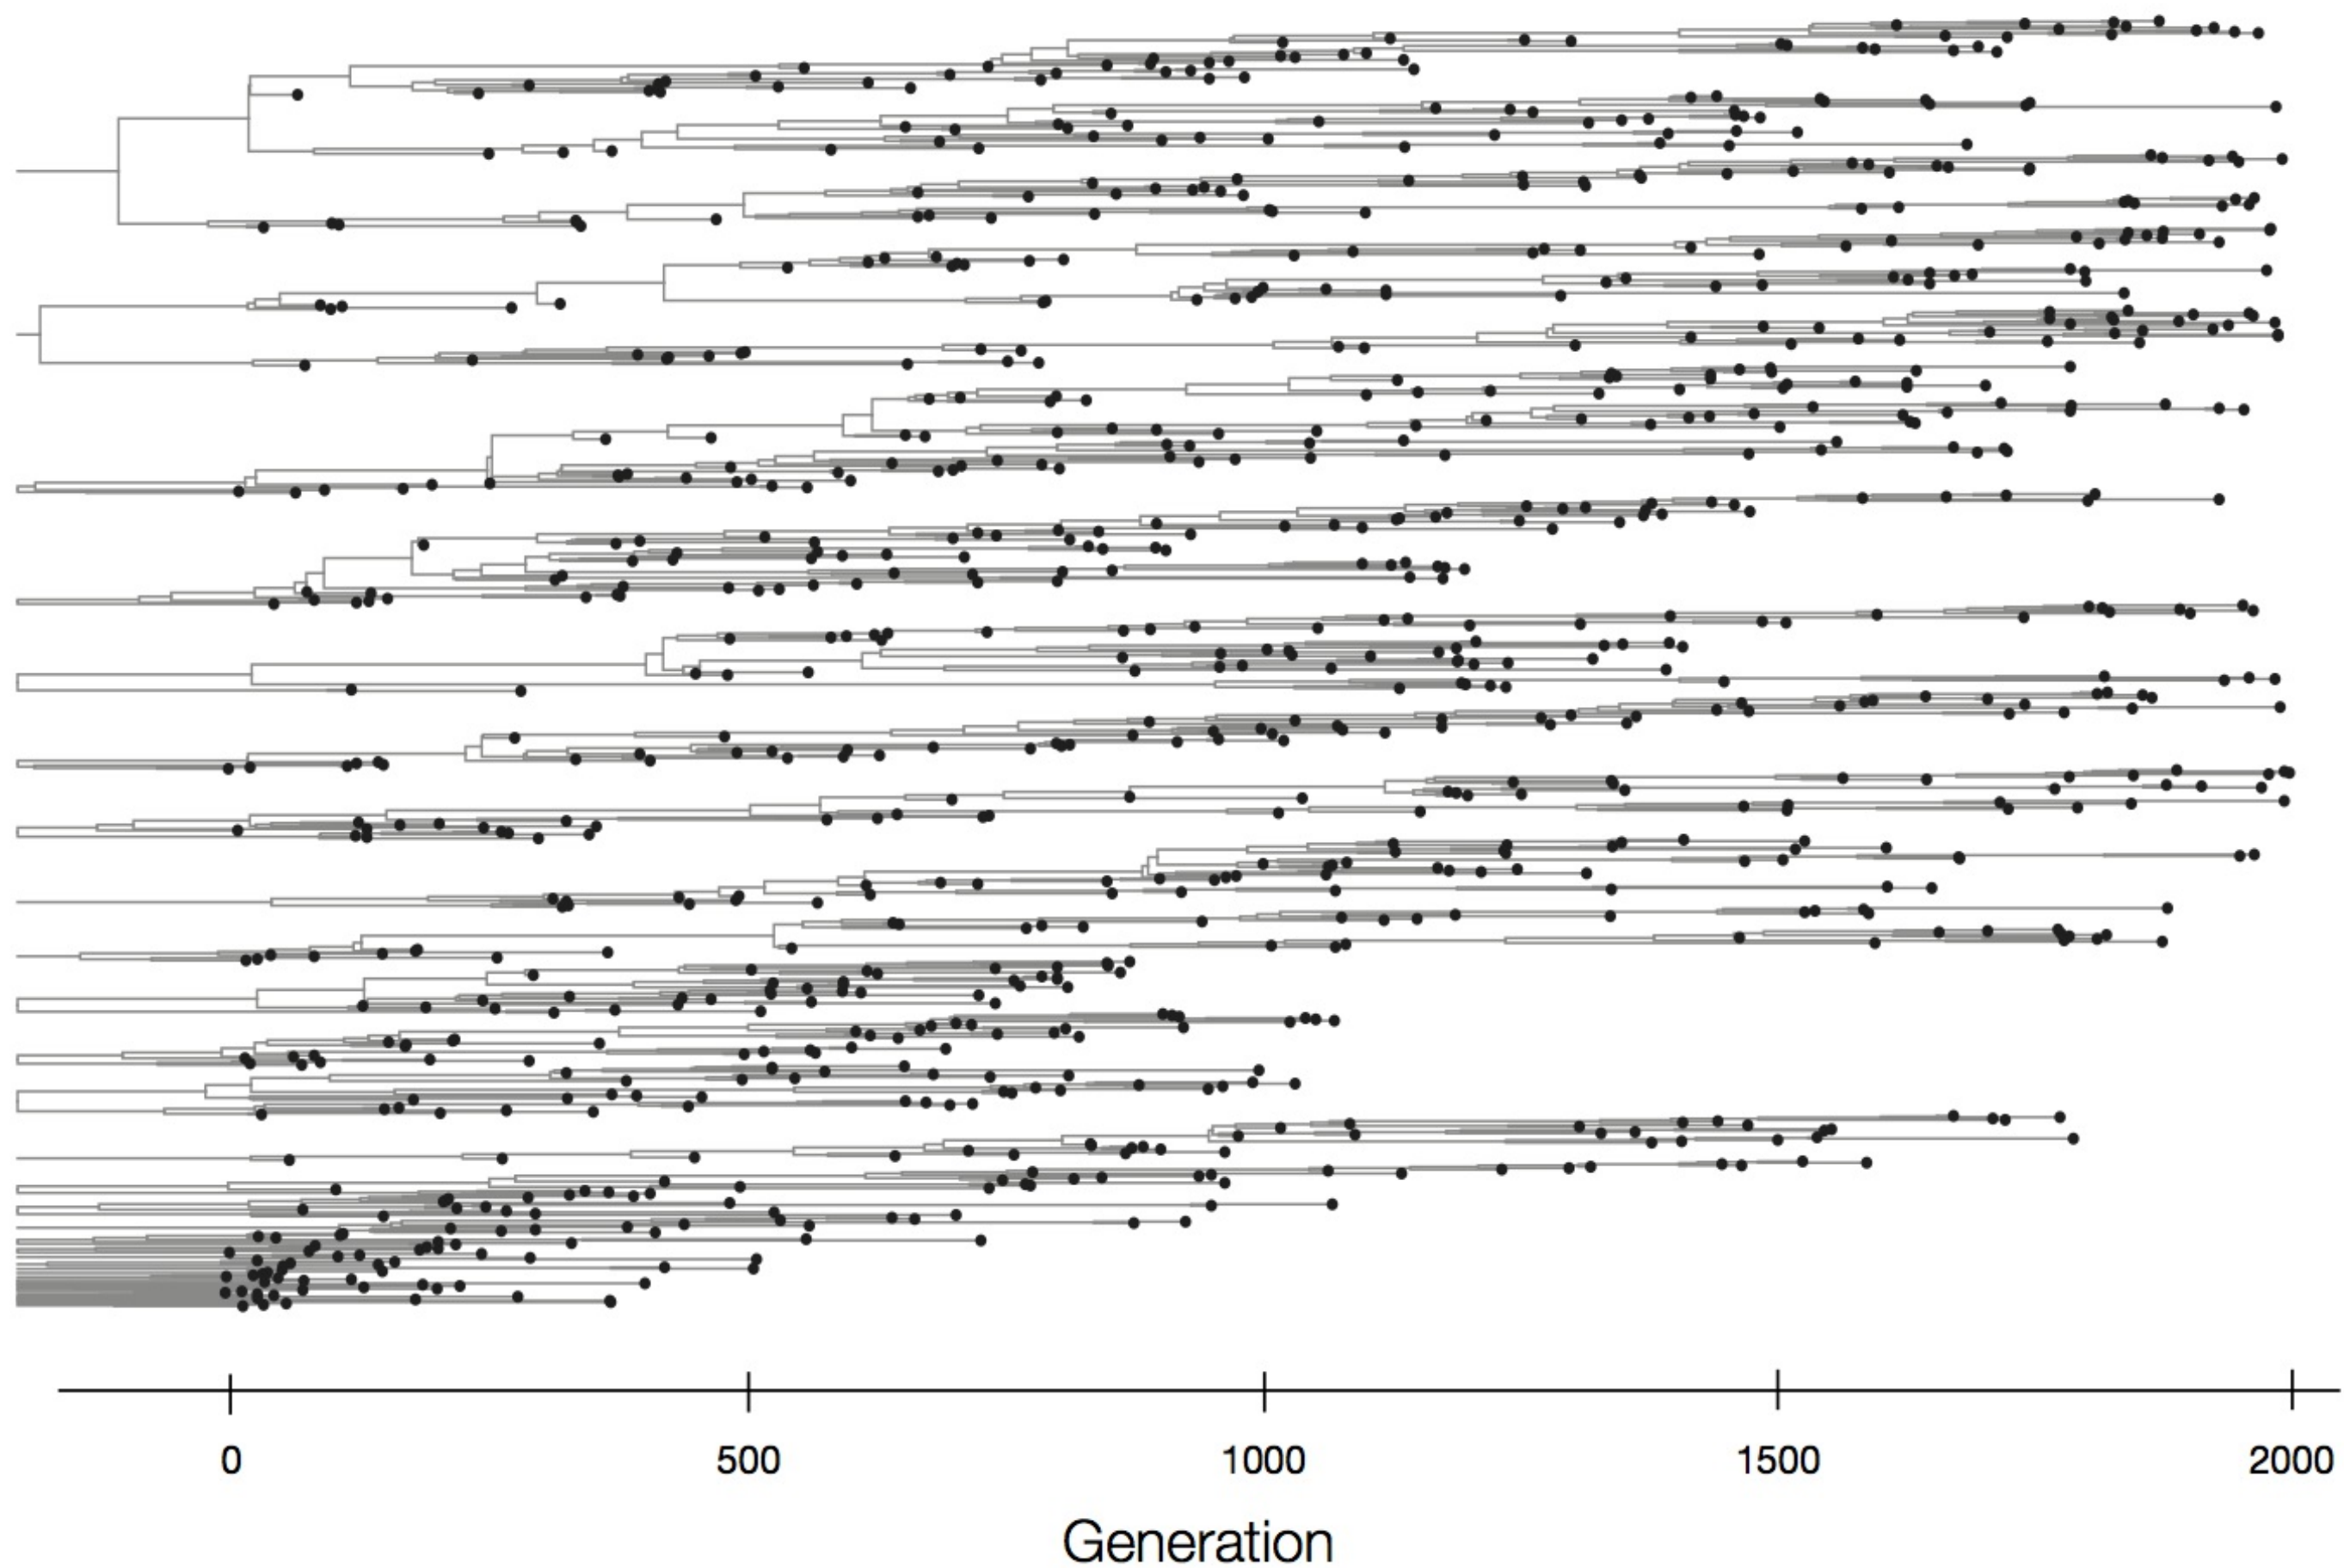

Exercise: plot skyline from tree

Selection distorts coalescence patterns

Neutral population dynamics

Purifying selection reduces genetic diversity and leads to population stasis

Positive selection reduces genetic diversity leads to population turnover

Episodic positive selection shows selective sweeps
